The first minutes after birth are a very vulnerable period for both mother and newborn. The care that is provided during this time is critical to ensure not only their immediate survival but also to improve their longer-term health and nutrition. Active management of the third stage of labor (AMTSL), the optimal timing of umbilical cord clamping, early skin-to-skin contact between mother and newborn, and early breastfeeding initiation are safe, effective, feasible and evidence-based care practices that should be offered by a skilled birth attendant to all mothers and their infants in the continuum of maternal-neonatal care.

What are the recommended practices and why are they essential for maternal and infant health and survival?

1. Active management of the third stage of labor (AMTSL)

What is it?

- AMTSL includes three steps:1,2

1) Administration of an uterotonic drug (e.g. 10 IU of oxytocin intramuscularly) soon after delivery of the infant to avoid uterine atony. If oxytocin is not available, 400-600 µg of misoprostol can be given orally.

2) Delayed clamping and cutting of the umbilical cord followed by delivery of the placenta by controlled cord traction: After clamping and cutting the cord, keep slight tension on the cord and await a strong uterine contraction. Very gently pull downwards on the cord while stabilizing the uterus by applying counter traction with the other hand placed just above the mother’s pubic bone.

3) Uterine massage immediately following delivery of the placenta, and every 15 minutes for the first two hours.

Why is it important?

- Fourteen million cases of postpartum hemorrhage (PPH) are estimated to occur annually on a global level.3 PPH is the leading cause of maternal mortality worldwide, contributing to 25% of all maternal deaths,4 and uterine atony is the most common cause of PPH.

- AMTSL has been shown to significantly reduce the incidence of PPH from uterine atony by 60%,4 the incidence of postpartum blood loss of 1 L or more and the need for costly and risky blood transfusions,1 and prevent complications related to PPH. AMTSL can not only help prevent the disability and death of a mother at delivery but also ensure a better chance at survival for her infant, as maternal and neonatal survival are inextricably linked.

2. Optimal timing of umbilical cord clamping

What is it?

- The optimal time to clamp the umbilical cord for all infants regardless of gestational age or fetal weight is when the circulation in the cord has ceased, and the cord is flat and pulseless (approximately 3 minutes or more after birth).5 After the infant is delivered and dried with a clean dry cloth, a fully reactive infant may be placed prone on the maternal abdomen and covered with a warm
dry blanket until cord pulsations cease and the cord is clamped and cut.

**Why is it important?**

- For the first minutes after birth, there is still circulation from the placenta to the infant, the majority of which occurs within three minutes, generally coinciding with the end of cord pulsations.

- Clamping the umbilical cord immediately (within the first 10 to 15 seconds after delivery) prevents the newborn from receiving adequate blood volume and consequently sufficient iron stores. **Immediate cord clamping has been shown to increase the incidence of iron deficiency and anemia during the first half of infancy,** with lower birth weight infants and infants born to iron deficient mothers being at particular risk. Up to 50% of infants in developing countries become anemic by 1 year of life, a condition which can negatively and perhaps irreversibly affect mental and motor development. According to one longitudinal study, Costa Rican children with chronic iron deficiency in infancy had 10 to 25 point lower cognitive test scores at 19 years of age, when compared to similar children with adequate iron status.

- Waiting to clamp the umbilical cord allows a physiological transfer of placental blood to the infant which provides sufficient iron reserves for the first 6 to 8 months of life, preventing or delaying the development of iron deficiency until other interventions—such as the use of iron-fortified foods—can be implemented.

- For premature and low birth weight infants, immediate cord clamping can also increase the risk of intraventricular hemorrhage and late-onset sepsis. In addition, immediate cord clamping in these infants increases the need for blood transfusions for anemia and low blood pressure.

3. **Early initiation of breastfeeding and mother-to-infant skin-to-skin contact**

**What is it?**

- As soon as the newborn is stable and breathing, he/she may be placed on the mother’s chest, prone, in skin-to-skin contact, with a warm, dry cloth covering the infant’s back and the mother’s chest. Routine delivery room procedures (such as cleaning and weighing) should be delayed for at least the first hour.

**Why is it important?**

- In addition to regulating infant temperature and enhancing maternal-infant bonding—essential for neonatal survival—immediate and uninterrupted skin-to-skin contact between the mother and infant promotes early initiation of breastfeeding and is associated with a longer duration of exclusive breastfeeding in infancy. Beginning breastfeeding immediately and exclusively (i.e. within the first hour) is fundamental to survival in the neonatal period and beyond: in Latin America and the Caribbean, it is estimated that 66% of infant deaths due to diarrheal disease and acute respiratory infection occurring between 0 to 3 months of age could be prevented by exclusive breastfeeding. Early breastfeeding also may benefit the mother, as suckling stimulates maternal oxytocin secretion, promoting uterine contractions and possibly reducing maternal bleeding. Routine delivery room practices that separate the mother and infant (such as cleaning and weighing the infant) have been shown to negatively impact early initiation of breastfeeding, as continuous, uninterrupted skin-to-skin contact may optimize the baby’s success at the first breastfeed. During this period together, health care staff should monitor the condition of both mother and newborn, and provide unobtrusive breastfeeding assistance if necessary, using an approach that takes into account maternal comfort and her desire for modesty.

**In summary**

These are evidence-based, cost-effective, safe and simple practices to reduce maternal morbidity and mortality and improve newborn and infant survival, health and nutrition.
To whom should these practices be offered?

All mothers should be offered AMTSL and immediate skin to skin contact with their infant after delivery and delayed cord clamping should be considered for every infant except in the case of asphyxiation where early cord clamping may be necessary in order to provide immediate resuscitative measures.

How can these practices be implemented together?

There are still remaining questions as to how to implement AMTSL with optimal cord clamping, in combination with early skin-to-skin contact and initiation of breastfeeding. A proposed sequence of steps based on potential feasibility and the available evidence supporting each practice is presented below. †

1. After delivery, immediately dry the infant. Then place the reactive infant, prone, on the mother’s abdomen.* Keep the infant covered with a dry cloth or towel to prevent heat loss.

   *If the infant is pale, limp, or not breathing, it is best to keep the infant at the level of the perineum to allow optimal blood flow and oxygenation while resuscitative measures are performed. Early cord clamping may be necessary if immediate attention cannot be provided without clamping and cutting the cord.

2. Give oxytocin (10 IU, intramuscularly) soon after delivery.

3. After cord pulsations have ceased (approximately 3 minutes after delivery), clamp and cut the cord following strict hygienic techniques.

4. Place the infant directly on the mother’s chest, prone, with the newborn’s skin touching the mother’s skin. While the mother’s skin will help regulate the infant’s temperature, cover both the mother and infant with a dry, warm cloth or towel to prevent heat loss. Cover the baby’s head with a cap or cloth.

5. Deliver the placenta by controlled cord traction on the umbilical cord and counter-pressure to the uterus.

6. Massage the uterus through the abdomen after delivery of the placenta.

7. During recovery, palpate the uterus through the abdomen every 15 minutes for two hours to make sure it is firm and monitor the amount of vaginal bleeding.

8. Aim to delay routine procedures (e.g. weighing, bathing) for at least the first hour so that mother and baby can be together in uninterrupted skin-to-skin contact and begin breastfeeding. If necessary, offer to assist the mother with the first breastfeed, being sensitive to her need for modesty.
